ML Expert Exercise

Task

Implement and train a Fully-Connected Neural Network (FCNN) model for segmenting an image into two classes in PyTorch. The network architecture is the following:

Input -> conv1 -> ReLu -> conv2 -> ReLu -> MaxPool 2x2 -> conv3 -> relu -> Upsample 2x2 -> conv4 -> Output

The input patch is of size WxHx3 (RGB), and the corresponding output patch is of size WxHx2.

The layer details follow:

conv1: 3x3, 16 channels, padding 1 conv2: 3x3, 32 channels, padding 1 conv3: 3x3, 16 channels, padding 1 conv4: 5x5, 2 channels, padding 2

Requirements

- Implement the code in Python 3 with PyTorch. You are allowed to use image loading modules such as skimage or PIL.
- Use GIT to keep track of changes and make commits as you consider necessary to keep track of your progress.
- To send us the code back, compress the contents of your code and git repository into a single file and email it to us.
- For training, write a script **train.py** that trains the network on the training image. Add the necessary code to plot the training loss as a function of the number of iterations. Assume that at some point we will train this algorithm on a GPU and that the network cannot fit in the GPU memory for an input image larger than 256x256x3.
- Write a script predict.py that predicts a trained network on the whole training image.

Notes

- We are aware the training set is very small and that the model may overfit. Our focus for this exercise is
 on the implementation and understanding of the network. There is no need to do cross-validation or early
 stopping.
- There is no need to run this on a GPU, we are satisfied with the code running on the CPU. In this way you will be able to try it on a laptop or your home computer.
- You may need to make some assumptions in order to implement the training and prediction code. If you
 have any questions don't hesitate to contact us.
